Subject: Change in Land Surface Model in Global Forecast System and Associated Cool and Moist Bias in Near Surface Temperature and Moisture Fields

Beginning with the 1200 Coordinated Universal Time (UTC) model run on Wednesday, September 5, 2012, the National Centers for Environmental Prediction (NCEP) Central Operations (NCO) will implement a fix to the Land Surface Model used to drive the Global Forecast System (GFS). This correction is expected to improve the cool and moist bias in the near surface air temperature and moisture fields during the warm season.

Starting in mid-June 2012, NCEP confirmed a problem with the GFS nearsurface temperature and moisture simulations. The model was not verifying in the late afternoon over the central United States when drought conditions existed. Specifically, users noted a significant 2m cold and wet bias in both the Model Output Statistics (MOS) and GFS gridded products. The NCEP Environmental Modeling Center (EMC) traced the problem to a look-up table used in the land surface scheme that modulates evapotranspiration based on vegetation type and root zone depth. Current settings allowed for excessive transpiration and plant-extraction of soil moisture from deeper soil layers, which caused the lower atmospheric boundary layer to become too moist and cool.

This summer, EMC conducted a parallel test of the GFS with corrected land surface parameters. EMC found the change to the land surface model significantly reduced the cold/wet bias over and improved the 0-3 day precipitation forecasts. An analysis of the parallel test results can be viewed here:

www.emc.ncep.noaa.gov/GFS/ppt/gfs lsm analysis 090412 final.pptx

In addition, the Meteorological Development Laboratory (MDL) evaluated the GFS MOS guidance generated from the GFS parallel output. MDL concluded the corrections in the GFS parallel output had the desired effect of reducing the cold/wet bias resulting in improved bias and error scores in the GFS MOS temperature and dewpoint guidance. Slight improvement was

also noted in the GFS MOS probability of precipitation guidance generated from the GFS parallel output. A summary of MDL's evaluation and comparisons of GFS MOS text bulletins generated from the GFS parallel output can be viewed at:

http://www.mdl.nws.noaa.gov/~mos/mos/gfs coolfix/comp mavmex.php

NCEP and MDL also conducted a 1.5-month GFS parallel evaluation from January-February 2012 to test the land surface model correction during the U.S. cold season. As expected, analysis of results indicated the change in the land surface model had little impact on the simulated 2m temperature and dewpoint given the low solar forcing during the winter months. MDL's analysis of the MOS guidance from the GFS parallel during the cool season sample also indicated minimal impact on the 2m temperature and dewpoint.

Based on the positive results of the GFS parallel tests and the severity of the cold and wet bias in the near surface air temperature, NCEP will implement the correction to the land surface model beginning with the 1200 UTC cycle on September 5, 2012. This change requires no action by users to continue receiving data.

NCEP thanks the users who alerted us to this problem. For questions regarding the correction to the GFS Land Surface Model and resulting improvement to the near surface cold and moist bias, please contact:

Bill Lapenta NCEP EMC/College Park, MD 301-683-3700 bill.lapenta@noaa.gov

For questions regarding the impacts on the GFS MOS text and gridded products, please contact:

Kathryn Gilbert MDL/Silver Spring, MD 301-713-0023, Ext. 130 kathryn.gilbert@noaa.gov

For questions regarding the impacts to the GFS LAMP text and gridded products, please contact:

Judy Ghirardelli MDL/Silver Spring, MD 301-713-0056, Ext. 194 judy.ghirardelli@noaa.gov
