What is El Niño?

The El Niño – Southern Oscillation (ENSO) is a recurring climate pattern where about 3 to 7 years climate conditions over the Pacific Ocean basin change dramatically. The extremes of this oscillation are referred to as El Niño and La Niña.

Normally, strong trade winds blow from the east along the equator, ocean waters are warm and rainfall is plentiful over the western Pacific, while over the central and eastern Pacific, ocean waters are cool and conditions are dry. During an El Niño event, sea surface temperatures over the central and eastern Pacific become warmer than normal.

The normal easterly trade winds weaken and sometimes, the winds will switch and blow from the west to the east! The result is drier weather conditions over the Western Pacific which can impact food and water availability, like taro.

Storms form closer to the islands and can increase flooding and sediment runoff from the land onto the coral reefs. This effect combined with slight sea level drops can cause coral die-offs and alter fishing habitats.

Associated with ENSO events are droughts, flash floods from severe storms, food and water shortages, and increase in health problems.

Every El Niño Differs!
The strengths and impacts of these events vary greatly making constant monitoring and awareness extremely important for decision makers to help you be prepared.

Summary for Guam & CNMI

<table>
<thead>
<tr>
<th>Rainfall</th>
<th>More rain in beginning of season; longer &amp; drier dry-season</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trade-winds</td>
<td>Weaker, with occasional westerly winds</td>
</tr>
<tr>
<td>Sea Level</td>
<td>Lower at first, gradual recovery in about 1 yr</td>
</tr>
<tr>
<td>Ocean Conditions</td>
<td>Cooler at and below the surface</td>
</tr>
<tr>
<td>Tropical Cyclones</td>
<td>Increased risk, storms form closer to islands</td>
</tr>
</tbody>
</table>
Weather Ready: Drought Preparedness

- Rainfall tends to be above normal during the first half of the El Niño year and starts to decrease around September. Dry conditions are usually their worst during February to May of the year after El Niño but can persist for longer.
- Water supply will decrease
- Farming & crops will be damaged
- Habitats for terrestrial and marine plants and animals will be stressed
- Health problems - bacteria in water and food, lack of food, and dehydration
- Wild fires risk will increase

Reduce water dependency & construct a rainwater catchment system (water good for 6 weeks)

Regional monthly rainfall during El Niño years

- Sea levels will drop below normal conditions by several inches up to nearly ½ foot during severely strong El Niño conditions
- During a moderate El Niño, sea level conditions are less severe and linger for less than 1 year
- Marine organisms will be impacted - spawning & reproduction will decrease
