The Shreveport National Weather Service

County Warning and Forecast Area

The National Weather Service Weather Forecast Office in Shreveport has forecast and warning responsibility for a total of **48 counties and parishes** over the four state area of Southeast Oklahoma, Southwest Arkansas, East Texas, and North & Central Louisiana.

The Shreveport National Weather Service Office

Weather observers began taking observations in 1871. By 1891, Shreveport became an official U.S. Weather Bureau Office in downtown Shreveport, and by 1940 the Weather Bureau was transferred to the Department of Commerce. Through the years, the Weather Service has gone from one daily surface weather map, to hourly weather observations, twice daily upper air observations, radar and satellite observations, and computer models. The National Weather Service in Shreveport is now located on Hollywood Avenue in Shreveport, LA, which is the 14th location in 140+ years of operation. Doppler Radar and the Upper-Air equipment are collocated with the office. Being on the fringe of tornado alley, the National Weather Service in Shreveport has been at the forefront of service to the public, and this will continue as new, cutting-edge technology becomes integrated into the forecast and warning process. We are constantly working with our partners to build a more resilient and Weather Ready Nation.

January 06, 2017 Winter Weather

An arctic air mass began to spill southward across the region during the morning hours on January 6th. An upper level disturbance then moved across the Red River Valley resulting in the development of light snow across much of SE Oklahoma, Extreme NE Texas, and SW Arkansas. Accumulating snow amounts ranged from around 0.5 inches or less across portions of Northeast Texas to between 1-2 inches across SE Oklahoma and SW Arkansas. A separate area of weak overrunning of warmer air atop the arctic cold front resulted in areas of sleet mixed with light freezing rain and light snow over portions of Deep East Texas...Northcentral, Northeast, and Central Louisiana. Freezing rain accumulations were less than one tenth of an inch and sleet accumulations were generally less than one-quarter inch. These light snow and ice accumulations resulted in hazardous travel conditions.

Enhanced Fujita Scale (EF-Scale)

EF Number Max. Est. Wind Gusts

0	65-85 mph
1	86-110 mph
2	111-135 mph
3	136-165 mph
4	166-200 mph
5	Over 200 mph

Dr. Ted Fujita, who developed the Fujita Scale, is conducting a storm damage survey with Ernest Ethridge, OIC of the WFOSHV, following the Dec. 3, 1978 devastating EF-4 Bossier City tornado.

11/05/13- EF-2 tornado damage near Marthville LA

Our four state area sees most tornadoes in April & late day, from 3 to 9 p.m.

01/21/17- EF-2 tornado near Natchez, LA
(photo courtesy of Sam Dierst)

HOW STRONG WAS THAT TORNADO?

Meteorologists are deployed from the National Weather Service to investigate areas where a tornado is thought to have occurred based on damage reports, storm spotter reports and radar indications. First, the type of damage is determined from a list of 28 Damage Indicators (DI). Examples include small barns, 1- or 2-family residences, retail buildings, and hardwood & softwood trees. Each DI is examined to determine the Degree of Damage, which is specific to the DI. This results in an EF-rating and an estimated range of peak wind speeds. If EF-4 or EF-5 damage is suspected, a second team is deployed to investigate the damage more closely and confirm the rating. Particular attention is paid to construction methods and materials when considering EF-4 or EF-5 ratings.

Tea Cup	3
Softball	4
Grapefruit	$4\frac{1}{2}$

HAIL

May 10 2006, a "Tail-end Charlie" supercell T'storm produced this 4+ inch hail stone which fell in Rocky Branch. During this evening, other storms moving East produced baseball sized hail affecting many cities in NE LA in the MS river delta region.

April 2, 2017, a strong upper level system brought widespread severe weather across the region. Numerous reports of Tornadoes, Wind Damage, and large Hail was received across the area. The picture to the left (courtesy of Larrah Springer) shows quarter to half dollar size hail from Columbia, Louisiana.

Skywarn Spotter: Mack Redmond, KA5JNL
Location: Rocky Branch, LA
Date: May 10, 2006

Photo: David Gore, WIS06

How does large hail form inside of a maturing thunderstorm in a half hour?

Tiny liquid water droplets are carried high up in the cloud tops by the main updraft. Air temps drop about 5 degrees for every 1000 ft. up. By 50,000 ft up in "Overshooting" cloud tops, the air is 50-60 degrees colder and even below freezing in late Spring & Summer. The drops coalesce or merge as they freeze into what is called graupel (small ice pellets). Additional layers of water continue freeze on the growing hail, making several trips up and down in the storm, building ice layers for 10-20 minutes. By this time, the weight of the large hail is just too much for the updraft winds to support and it then falls to the Earth at speeds of 100 mph. The good news is that as these largest of hail stones fall into warming air and thus shrink a bit in size before impact. The updraft's strength is the key to hail sizes and is maximized with peak daytime heating and occurring potentially year round. Some hail forms in all T'storms thus making lightning through friction, like your slippers do in Winter.

Hot spots by month

Category classifications based on wind speed of hurricanes

Cat 1	Cat 2	Cat 3	Cat 4	Cat 5
74-95 mph	96-110 mph	111-129 mph	130-156 mph	157+mph

- **Tropical Depressions** form & are given a number when cyclonic surface winds are developing & are less still less than 39 mph.
- **Tropical Storms** are named when the surface wind speeds reach 39 mph or more .
- **Hurricanes** assume the named tropical storm when surface winds reach 74 mph or more.

Heat Index
(Apparent Temperature)

With Prolonged Exposure and/or Physical Activity

Extreme Danger

Heat stroke or sunstroke highly likely

Danger

Sunstroke, muscle cramps, and/or heat exhaustion likely

Extreme Caution

Sunstroke, muscle cramps, and/or heat exhaustion possible

Caution

Fatigue possible

HEAT EXHAUSTION

OR

HEAT STROKE

Faint or dizzy

Excessive sweating

Cool, pale, clammy skin

Nausea or vomiting

Rapid, weak pulse

Muscle cramps

• Get to a cooler, air conditioned place

• Drink water if fully conscious

• Take a cool shower or use cold compresses

Throbbing headache, confusion

No sweating

Body temperature above 103°
Red, hot, dry skin

Nausea or vomiting

Rapid, strong pulse

May lose consciousness

CALL 9-1-1

- Move person to cooler place
- Cool using cool cloths or bath
- Do not give anything to drink

straight line winds
near 90 mph

What is a Downburst?

A downburst is a column of rapidly sinking air from an intense thunderstorm that spreads out all in all directions after reaching the ground. Typically, this will create very strong winds at ground-level and can cause damage over wide swaths of land. Downbursts can produce straight-line winds of over 150 mph. That can produce damage comparable to an EF-3 tornado!

Why Do Leaves Change Color in the Fall?

Leaves get their green color from chlorophyll. This is needed in the process of photosynthesis, where trees use sunlight to change carbon dioxide and water into glucose. Trees will use glucose for energy and as a building block for their growth. As we move from Summer into Autumn, the days will become shorter, at which point there is not enough light or water for photosynthesis. As a result, trees are not able to process enough glucose for energy, and the chlorophyll begins to disappear from their leaves. As the bright green color in the leaves fade away, we begin to see more yellow, orange, bright reds, and purples before the leaves eventually fall and die.
