NOAA Model Performance

- The following charts were produced from AQI data from Airnowtech;
- The NOAA 06z Day 2 model run was plotted against the observed AQI values;
- The early season events of May 17-19 and June 10-13, 22 were generally under-predicted;
- July 22 was a notable over-prediction for the coastal sites.

Danbury and Cornwall (Western Interior)

Danbury Modeled AQI (06z before) vs Observed AQI

- The May and June events were under-predicted.

Cornwall Modeled AQI (06z before) vs Observed AQI

Westport and Stratford (West Coastal)

Westport Modeled AQI (06z before) vs Observed AQI

The May and June events were mostly under predicted.

Stratford Modeled AQI (06z before) vs Observed AQI

Groton and Madison (East Coastal)

Groton Modeled AQI (06z before) vs Observed AQI

The May and June events were better for Groton but missed Madison in May.

Madison Modeled AQI (06z before) vs Observed AQI

Hartford and Middletown (Central CT Valley)

Hartford Modeled AQI (06z before) vs Observed AQI

The May 17th event was under-predicted with over-prediction on July 19-20 in Hartford.

Middletown Modeled AQI (06z before) vs Observed AQI

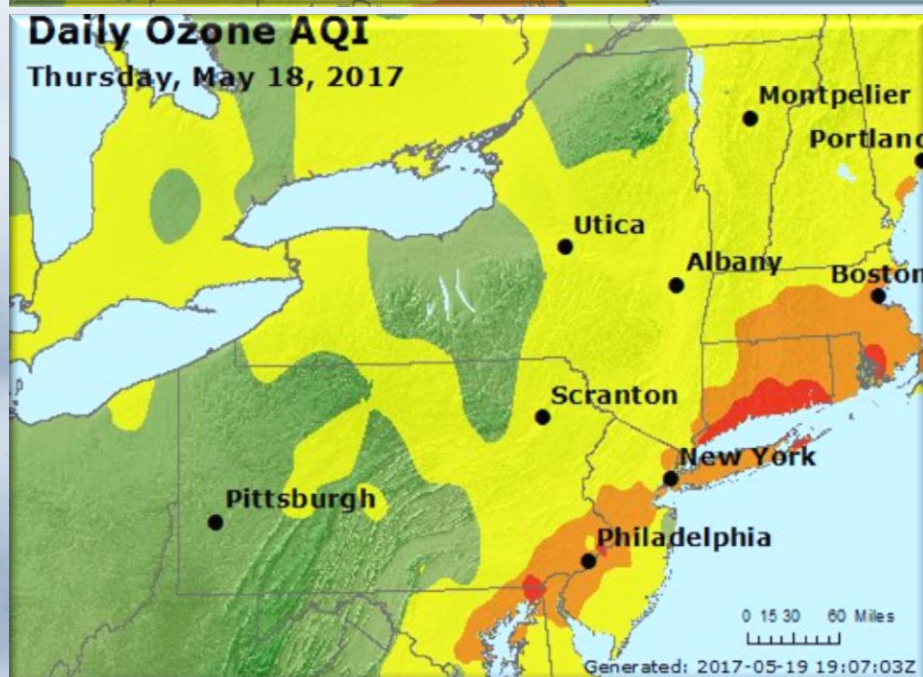

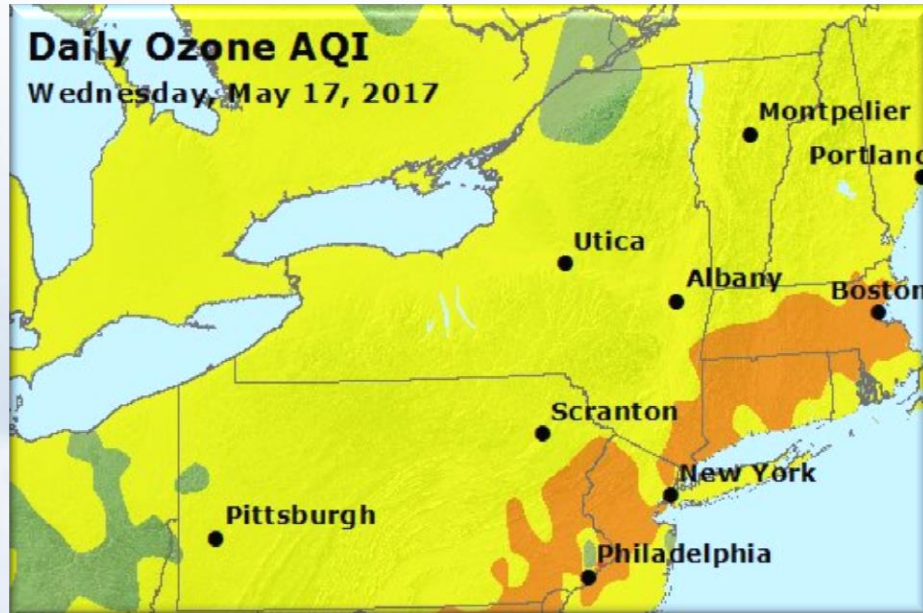

Connecticut Ozone Event May 17-19, 2017

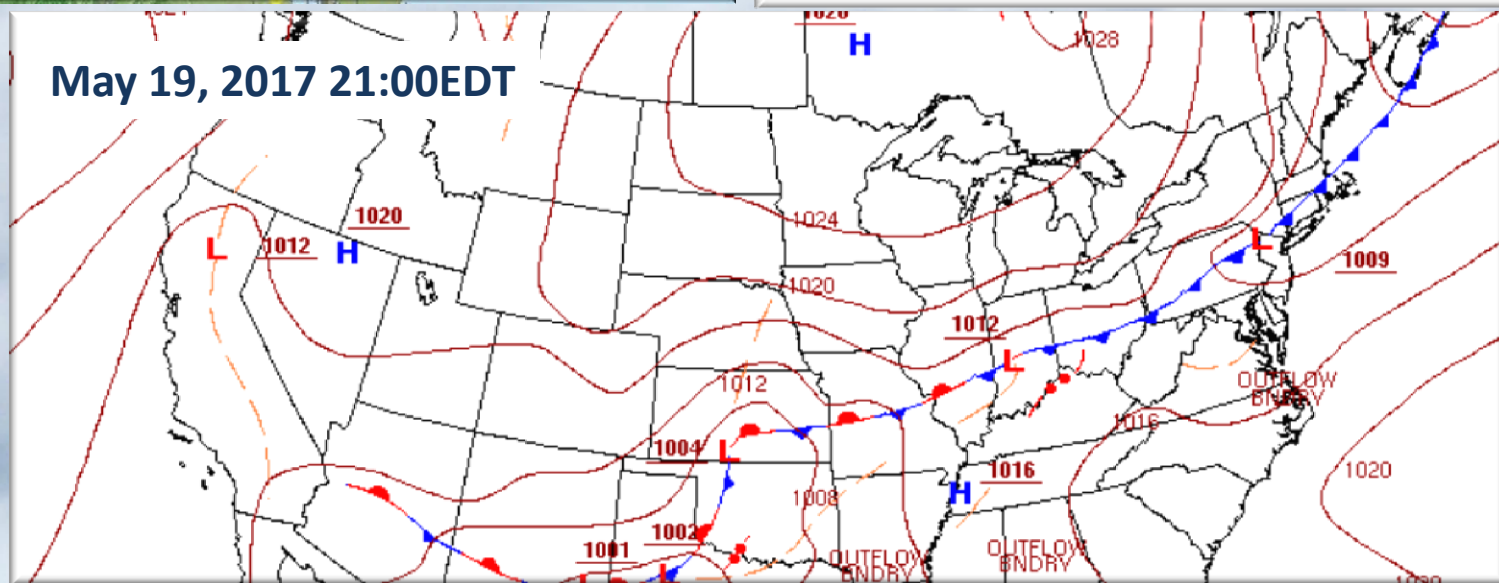

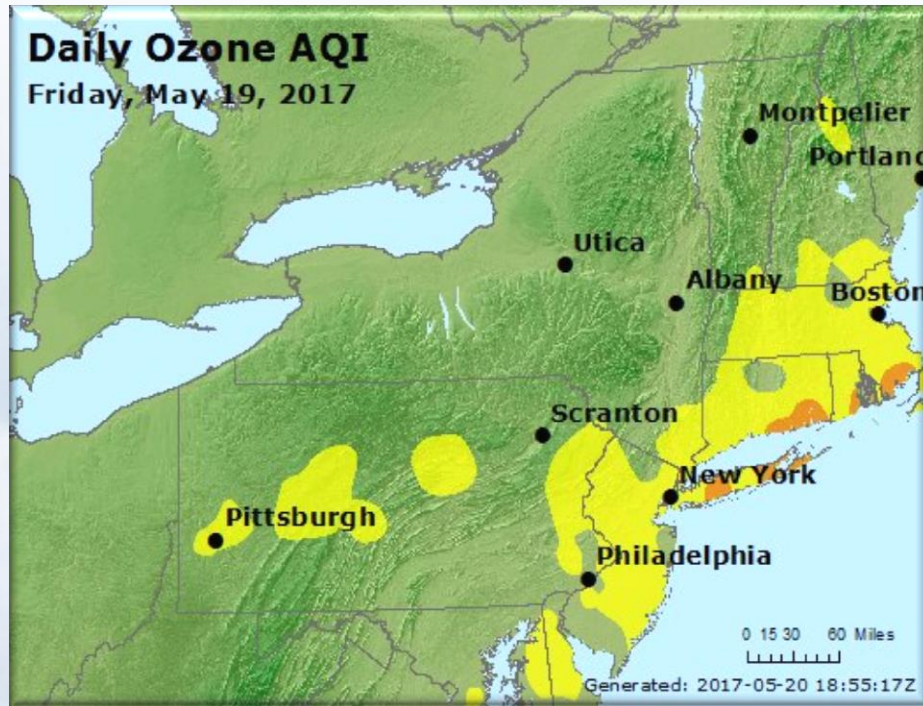

- This was a classic and widespread 3-day event for the I-95 corridor that quickly developed from a Bermuda high that setup off the east coast.
- All models correctly forecasted a USG event for the region but underestimated the areal extent, as the ozone plume pushed much further inland.
- The NOAA model doesn't assimilate gaseous smoke emissions into their ozone model, so that may have been responsible for some of the under predictions.
- Inland areas commonly have higher ozone levels earlier in the season than the coast, possibly because the sea breeze has a greater effect of pushing the plume inland than later in the season. A finer grid model resolution would be useful here.

GrADS: COLA/IGES

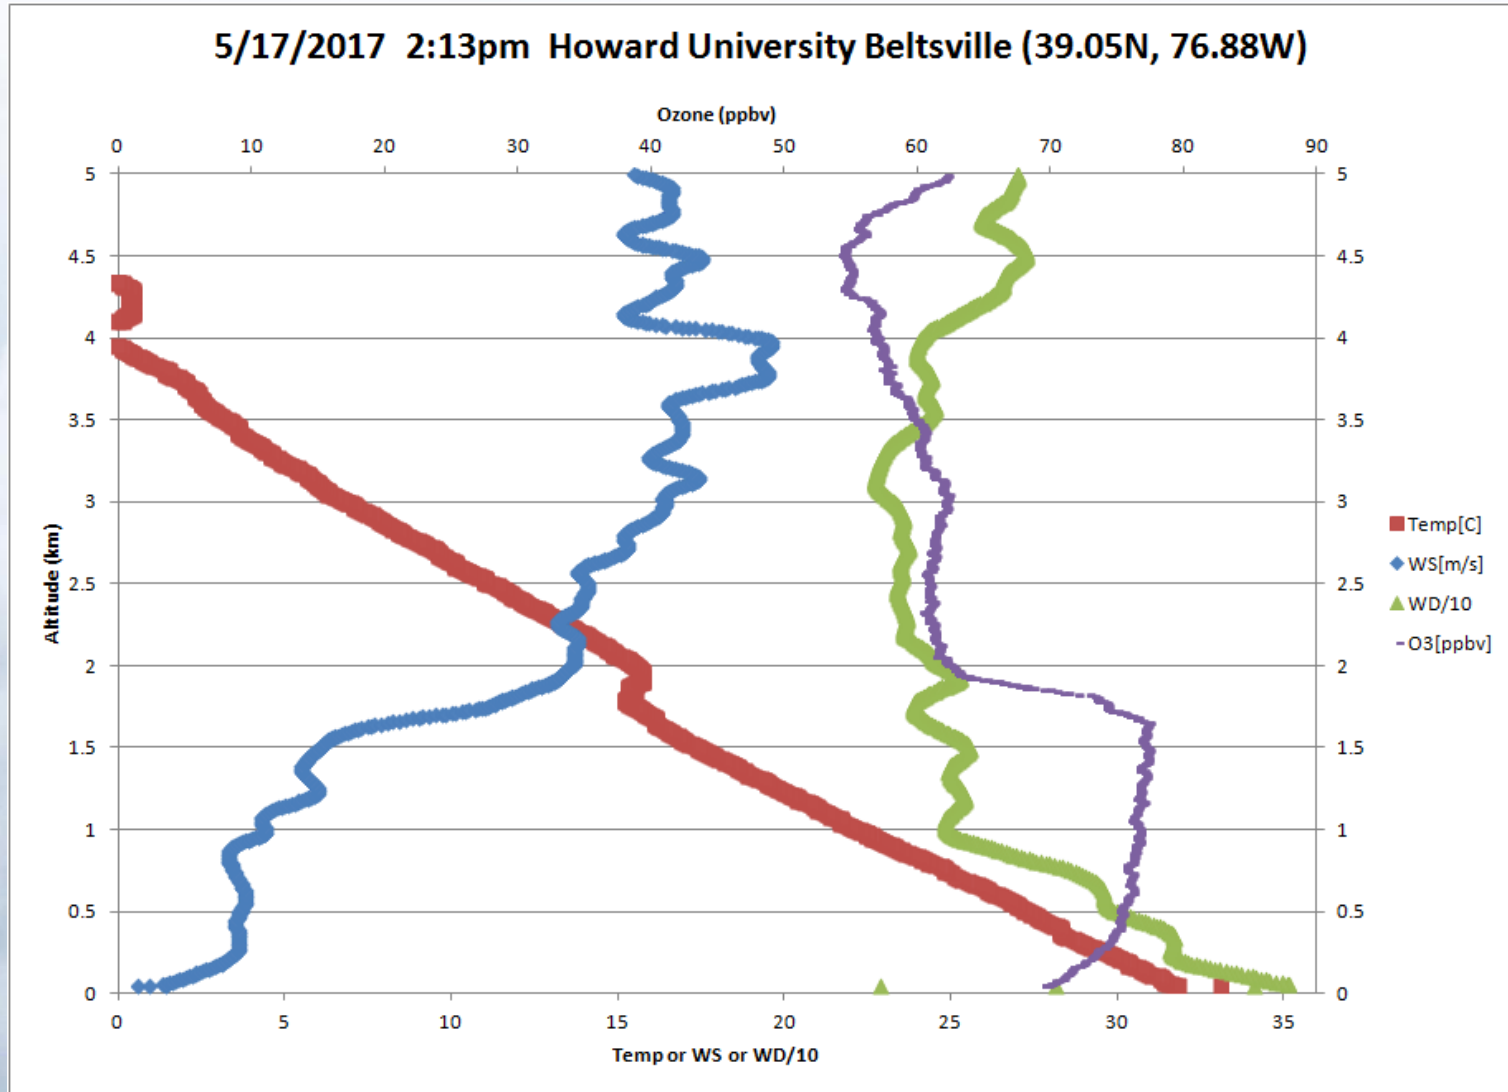

Agricultural burning from Mexico and the southeast States was advecting smoke towards the Mid-Atlantic States and New England

May 18, 2017 Satellite and AOD

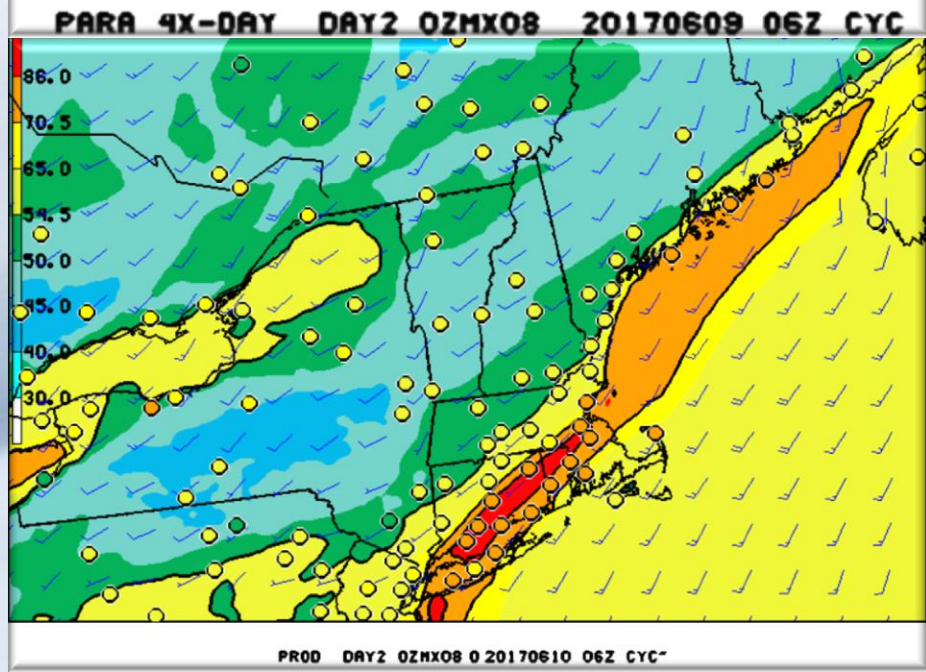

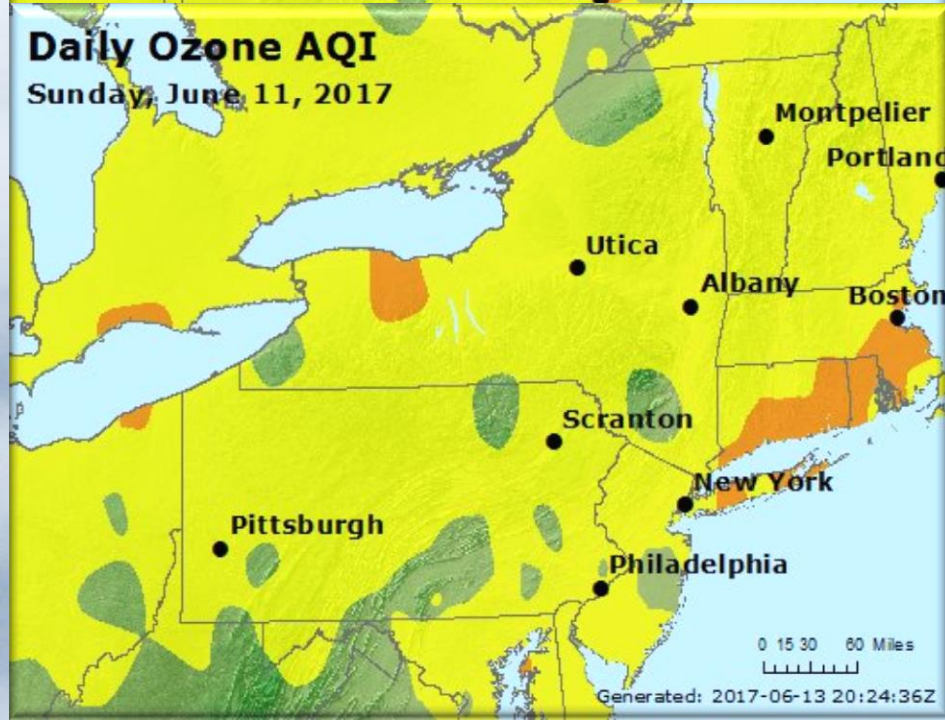

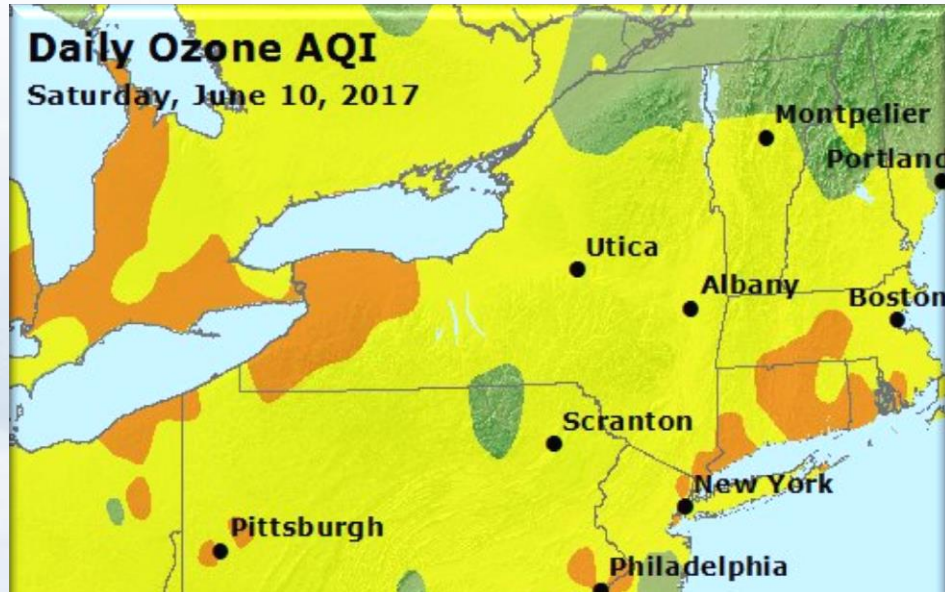

Residual aerosols from agricultural burning may have contributed to an increase in regional ozone.

Ozonesonde from Beltsville, MD on May 17, 2017

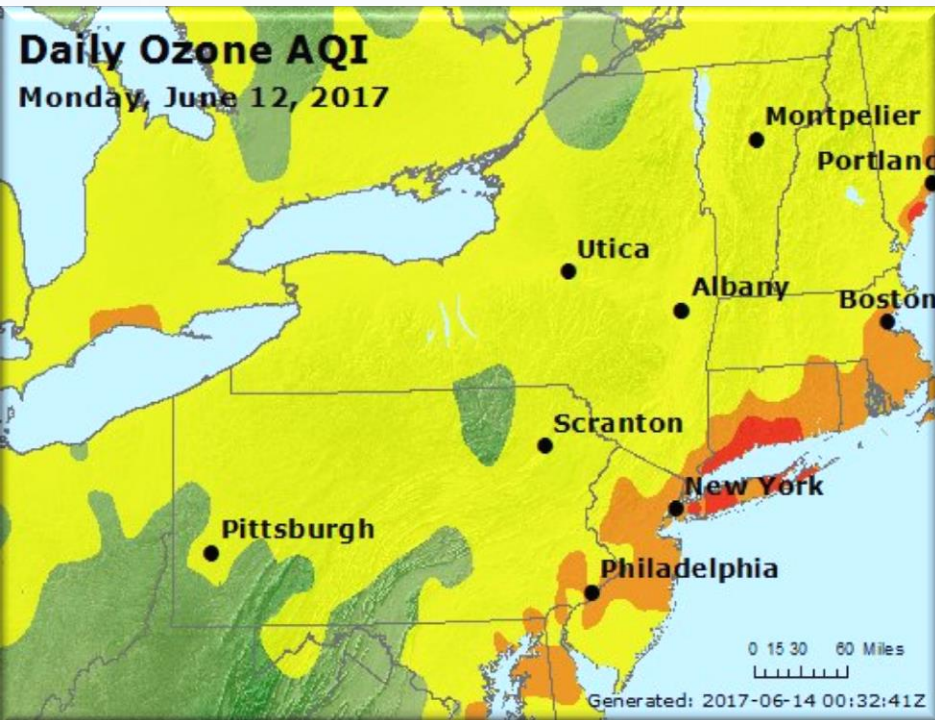

Ozonesonde shows an elevated reservoir of ozone between 500-1800 meters above the surface from a wind direction of about 250 degrees (west-southwest)

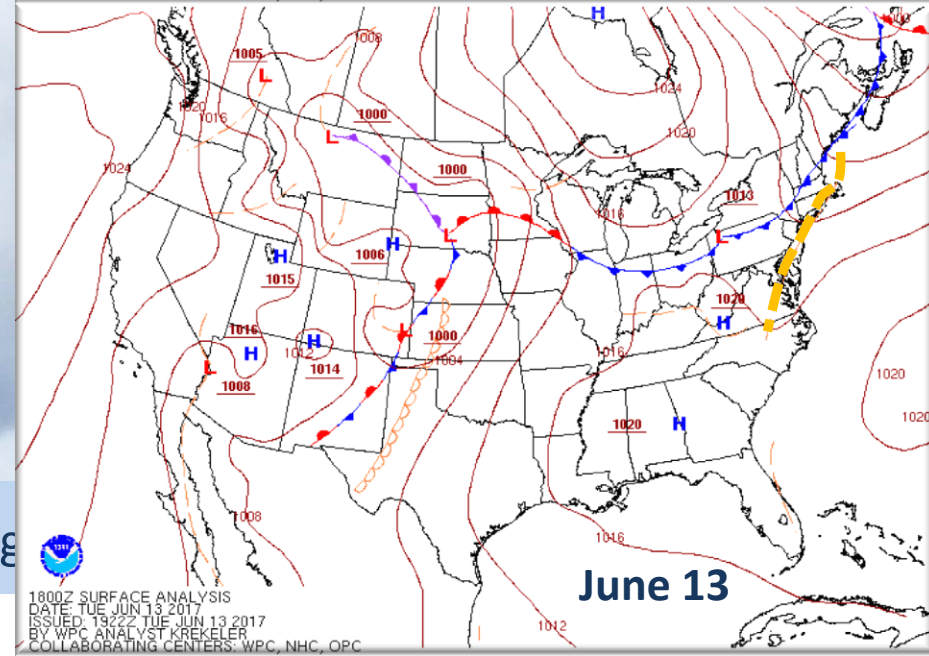

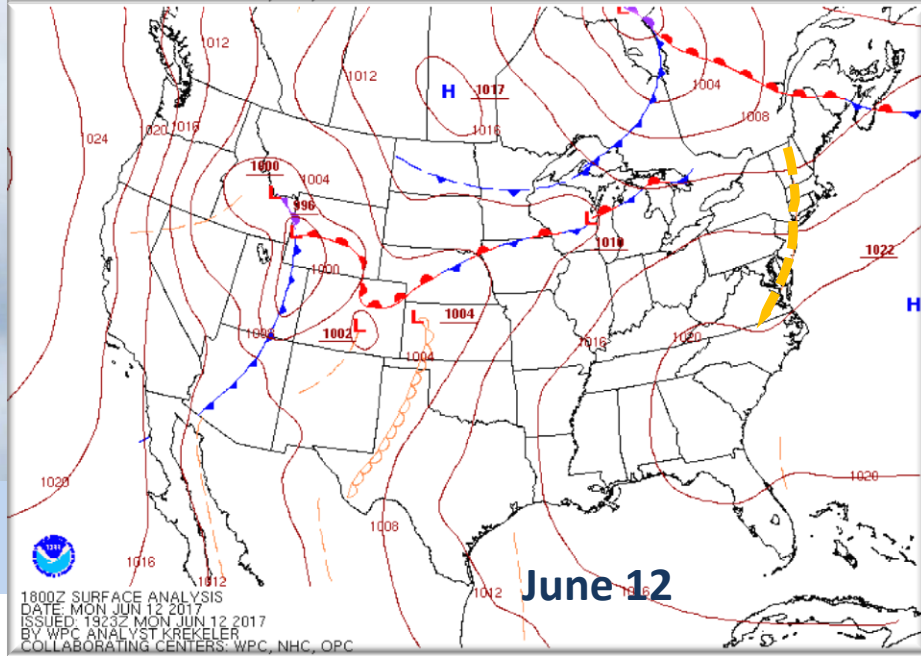

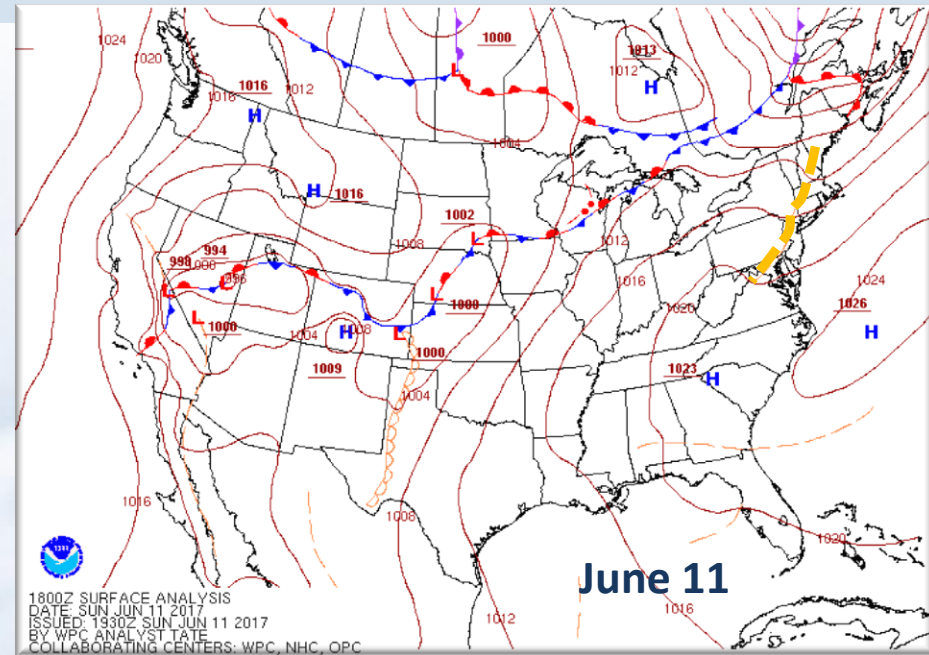

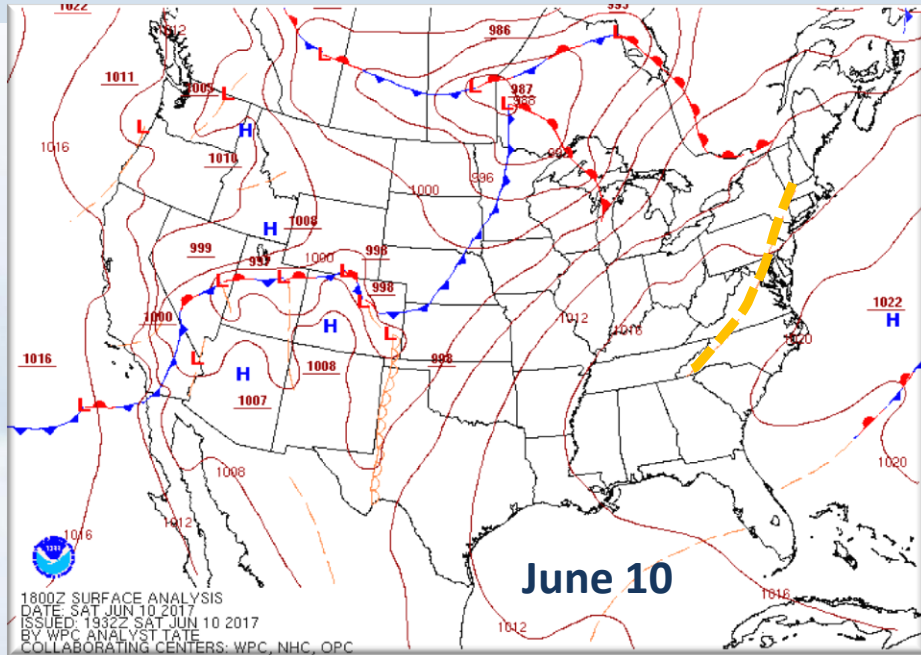

June 10-13, 2017 Ozone Event

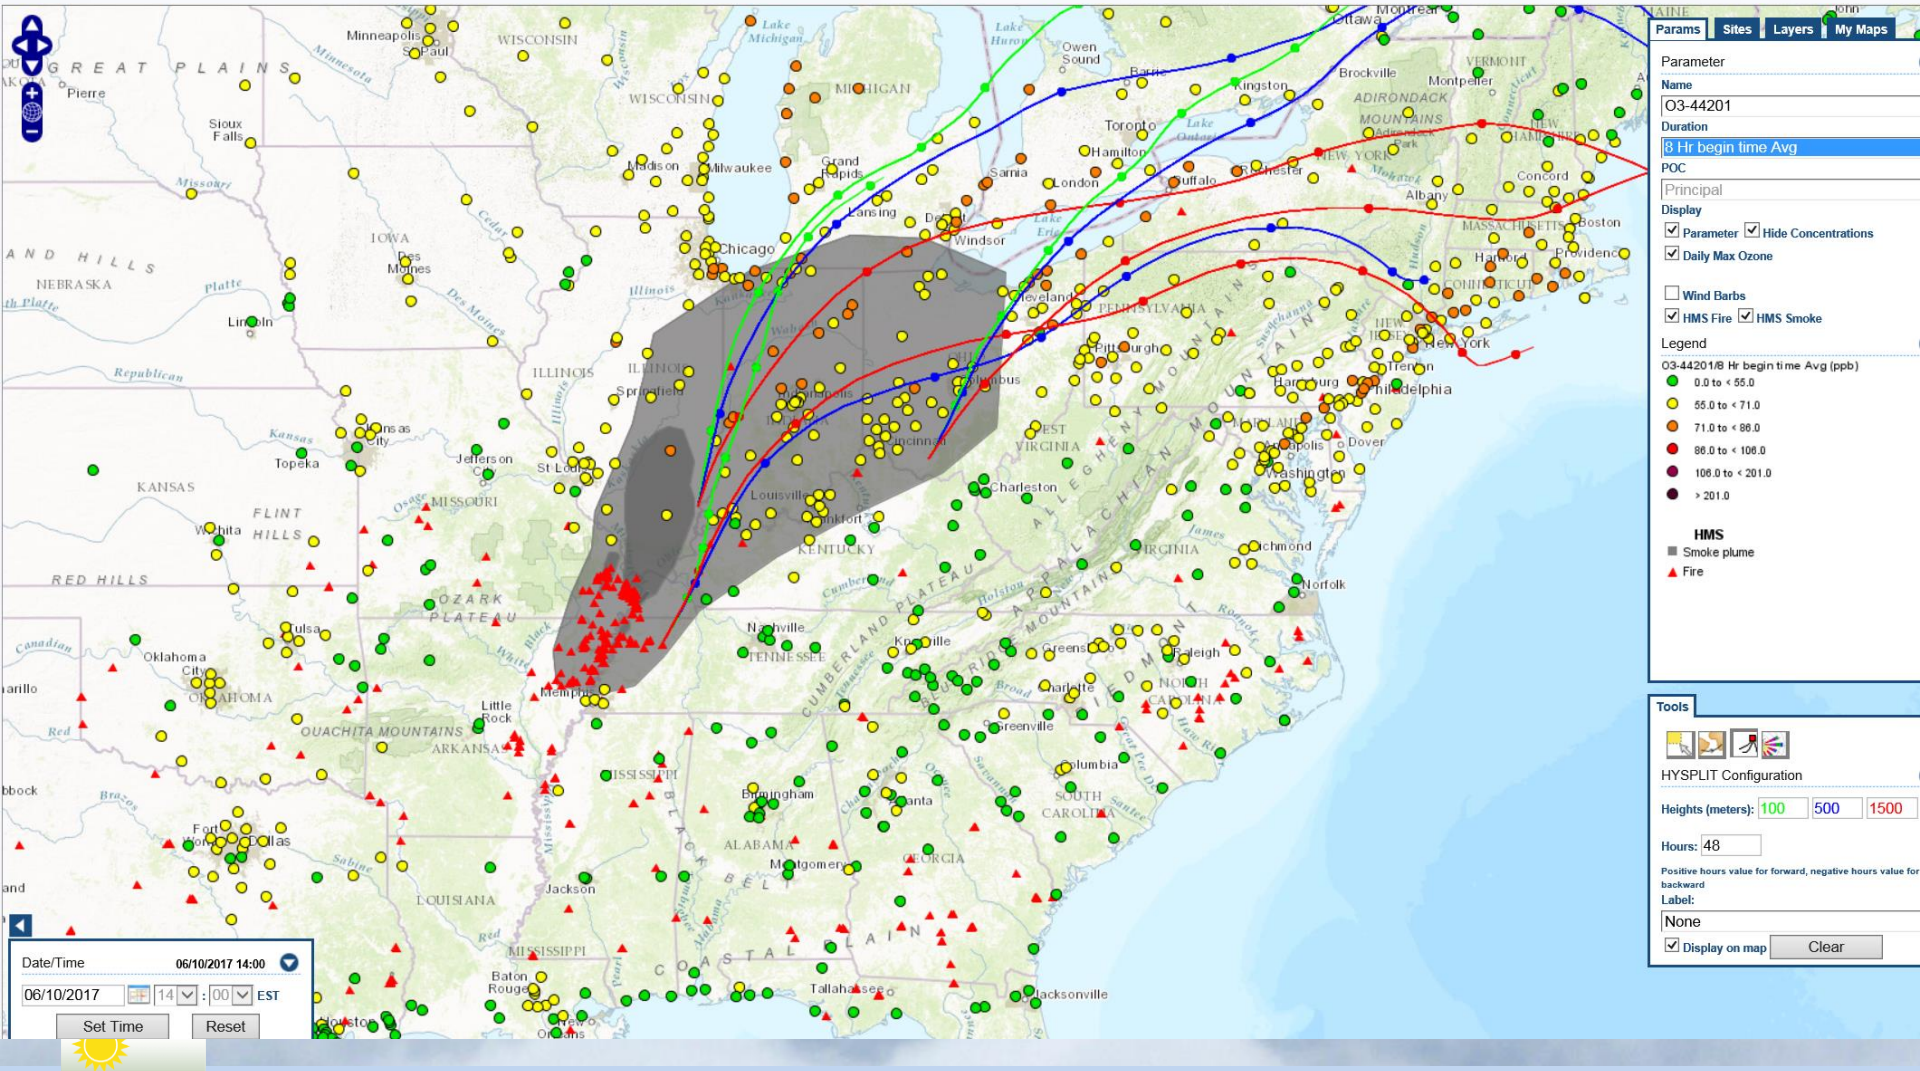

June 10-13, 2017 Ozone Event

18z Surface Maps with Lee Troughs

Trajectory Analysis June 10, 2017

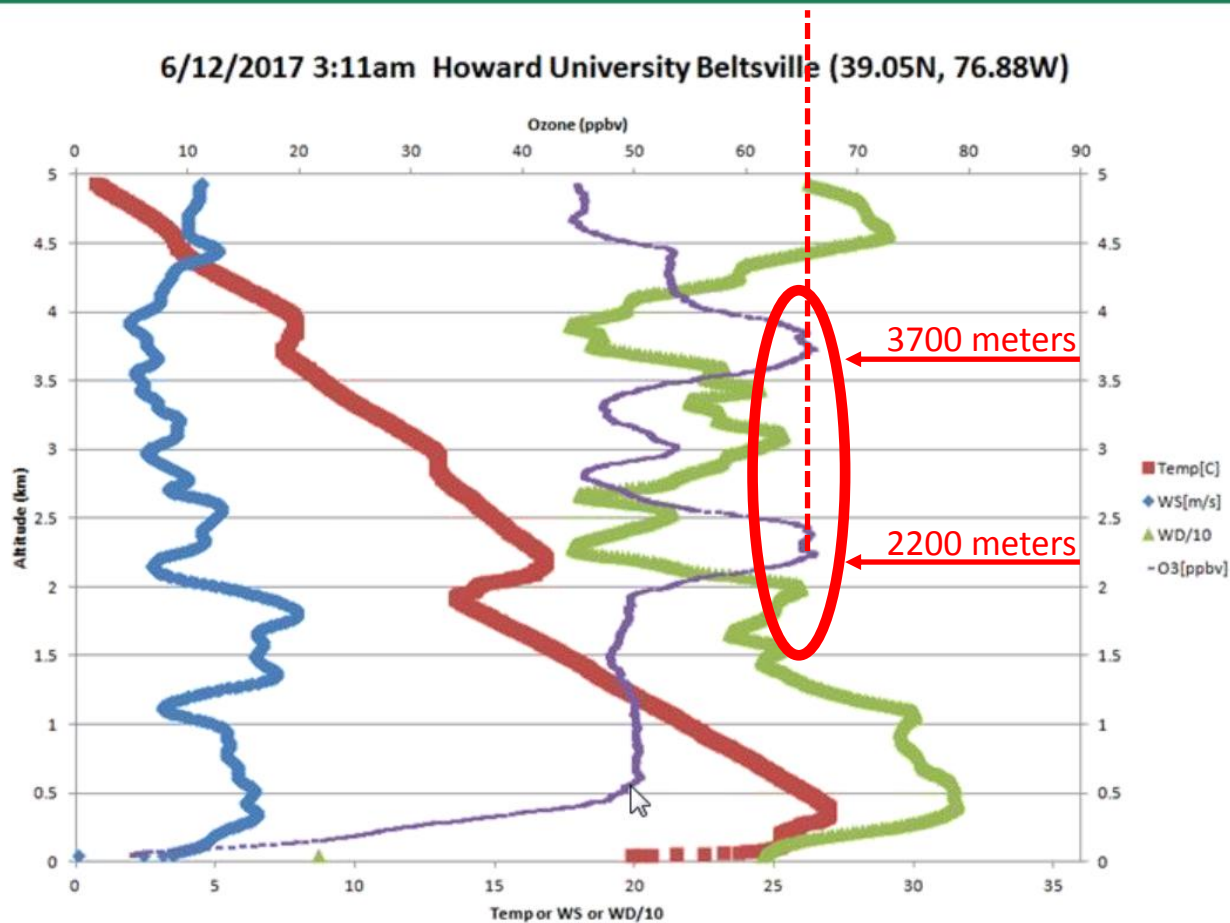

Fires from that same area were producing a sizable plume and 48 hour trajectories were entering New England from the west and northwest.

June 12, 2017 Maryland Ozonesonde

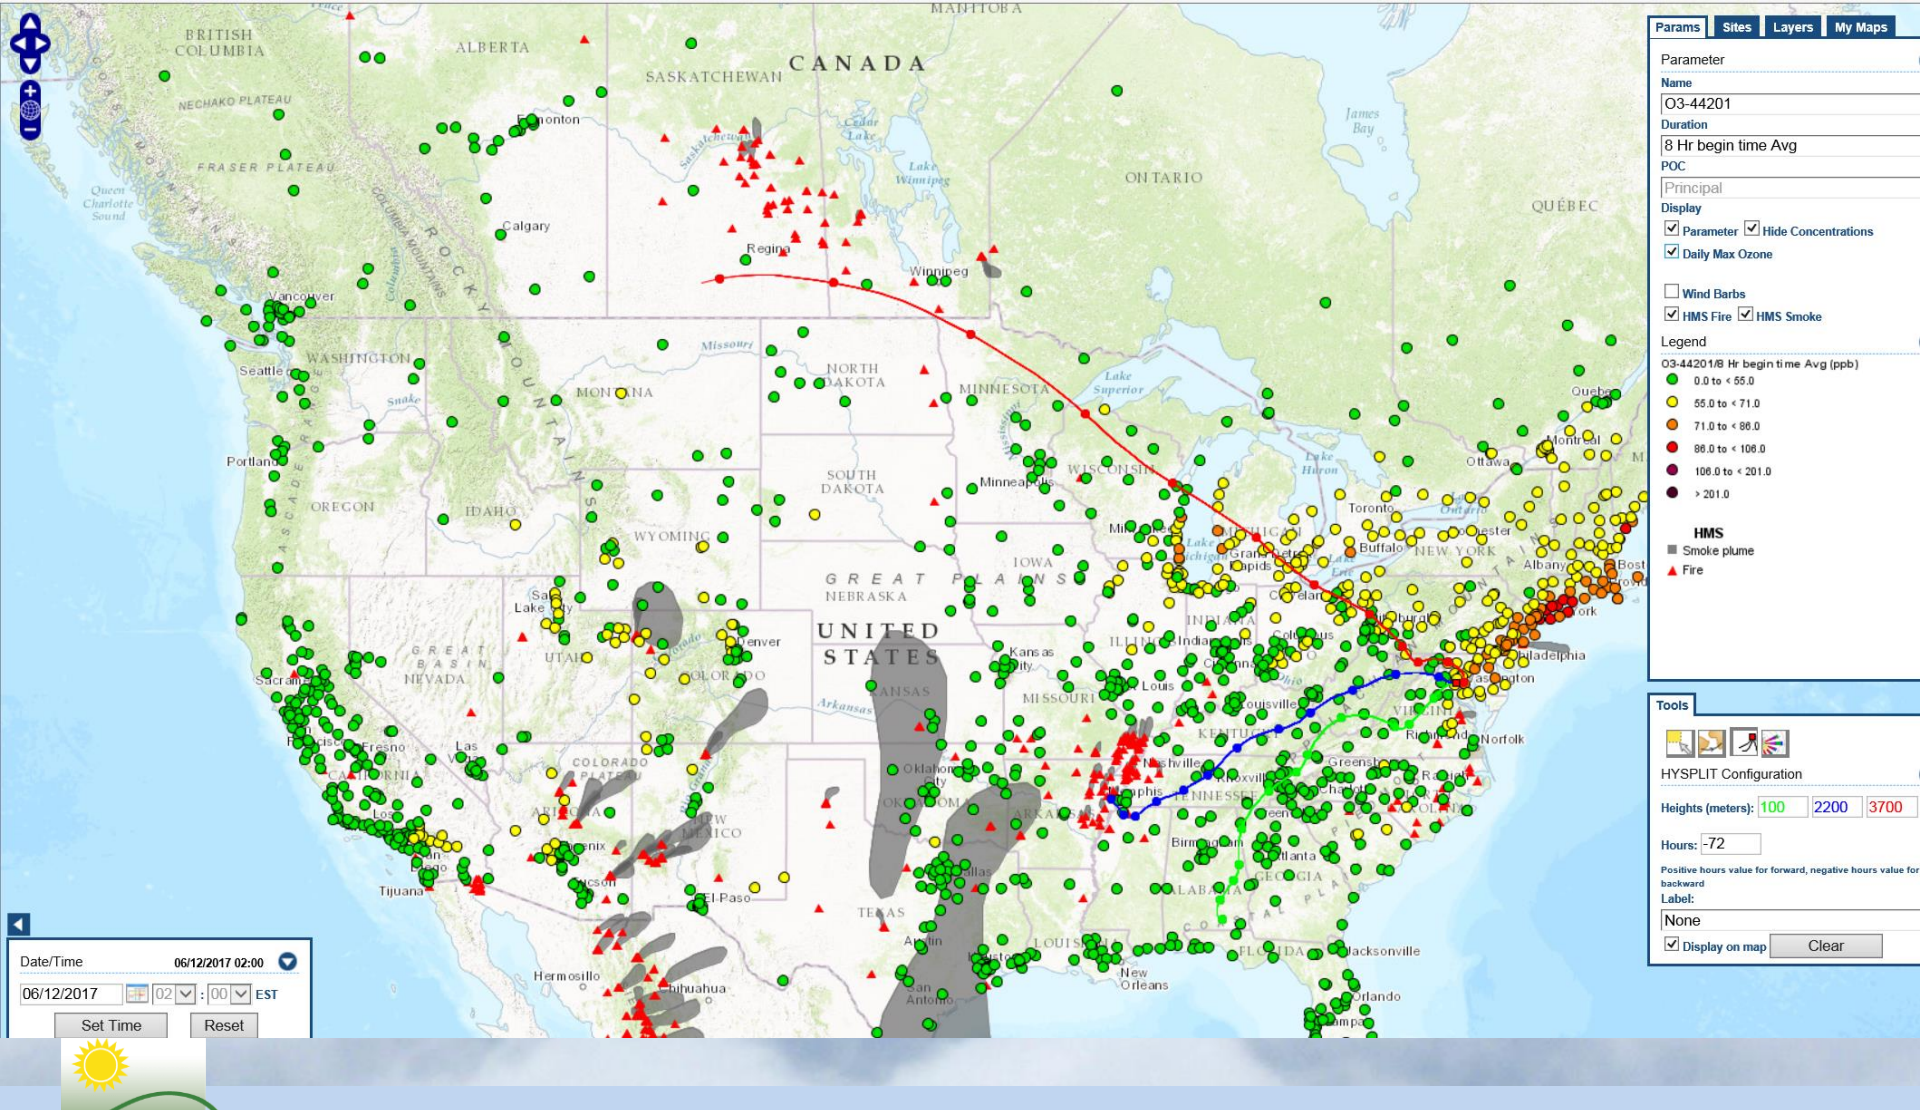

Early Morning Ozonesonde

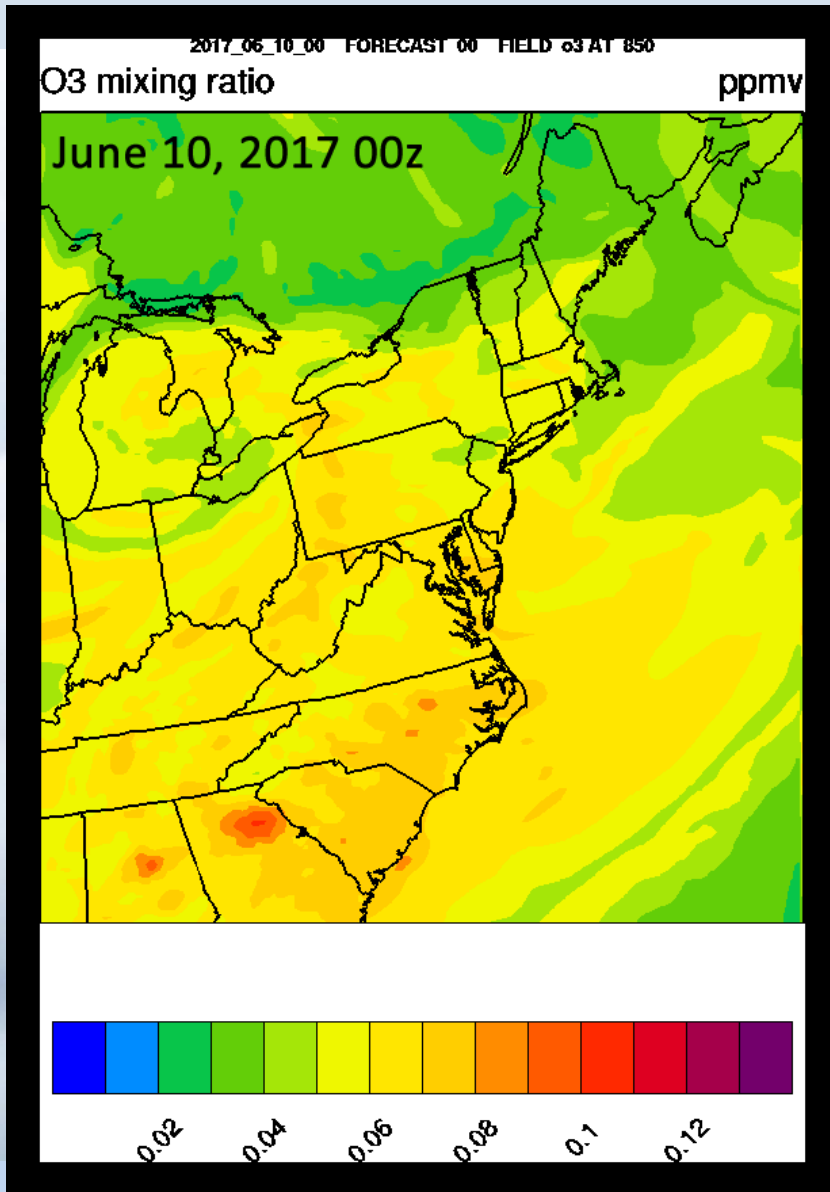

Note the elevated ozone levels of 65 ppb measured at layers 2200 and 3700 meters above the surface.

Beltsville Back Trajectory Analysis, June 12, 2017

The 2200 meter 72 hour back trajectory are from the region over the fires, while the 3700 meter back trajectory could have originated from fires in southern Canada.

WRFChem 850 mb Ozone

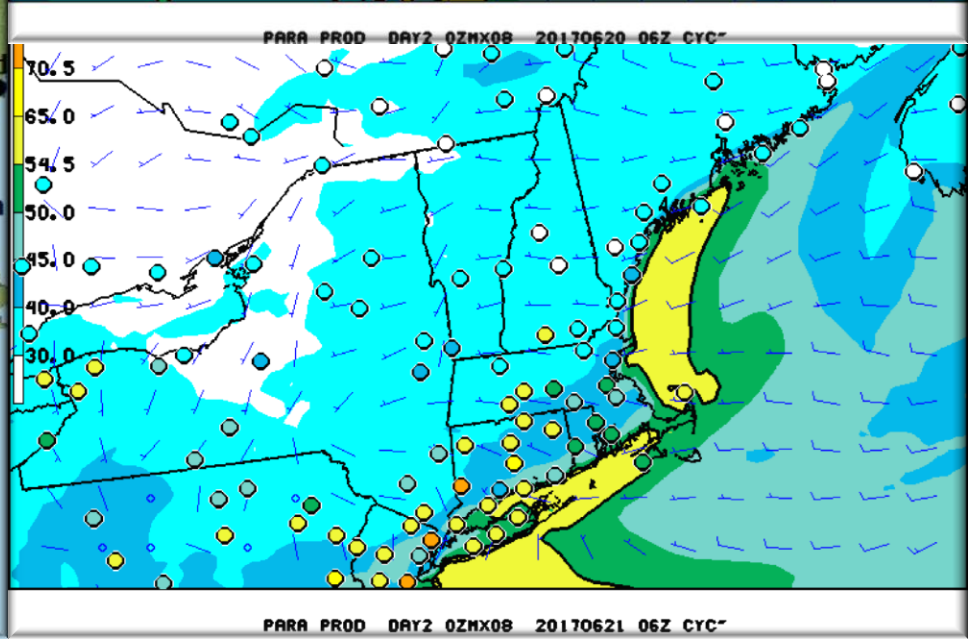

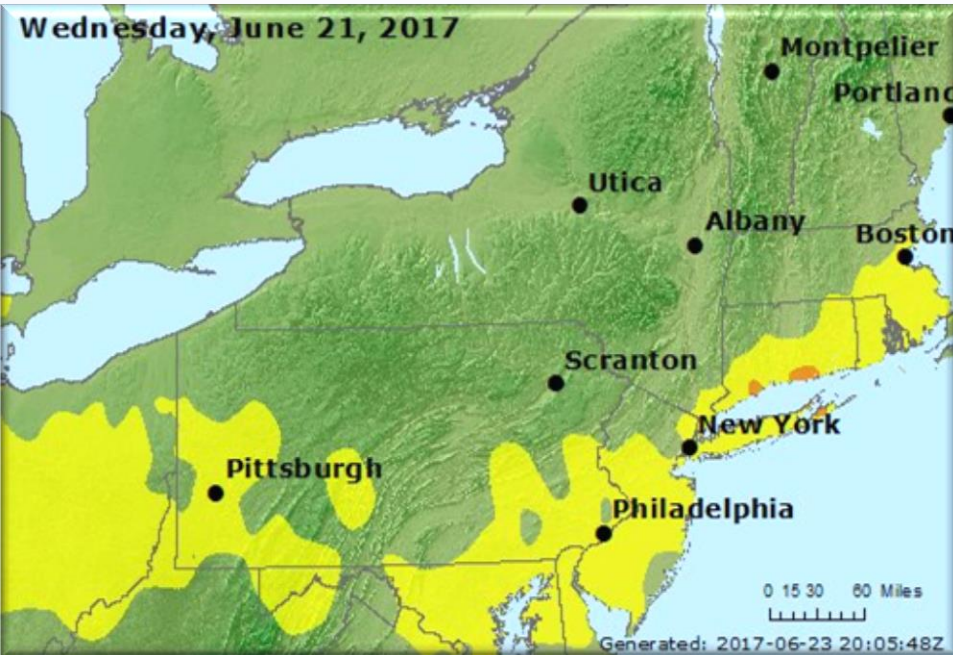

WRFChem was predicting a reservoir of 70+ ppb ozone residing above the eastern States at 850mb (~1500m). At 12z on June 12th, elevated ozone of 60-80 ppb was modeled just west of Beltsville, MD.

June 10-13, 2017 Ozone Event

- 2nd ozone event of the season in CT was driven by the Bermuda High circulation over the I-95 corridor with higher level transport from the west;
- Exceedances occurred from Maryland to Maine, with Cadillac Mountain monitoring the highest 8-hour ozone average of 98 ppb;
- NOAA ozone models provided good guidance and CT forecasters correctly forecasted exceedances on June 11-13th;
- NOAA model under prediction, especially on June 10th, likely due to smoke enhancement.

June 21-22, 2017 Ozone Event

June 21, 2017 Satellite AOD

The satellite AOD analysis shows elevated PM2.5 levels in the atmosphere, likely due to smoke emissions.

June 22, 2017 Surface Analysis 5:00pm

- Warm front was analyzed to the south of CT but lee-trough to our south may have created a southwest wind flow at the surface that allowed ozone to be transported from NYC into southwest CT.

June 22, 2017 WRFChem 850 mb Animation

- 850mb (~1500m) ozone (left) and 850mb organic aerosol (right) model animations show a clear connection with the transport of ozone with the aerosols from fires to our west.
- Note that tropical storm Cindy can be seen in the ozone circulation in east Texas.

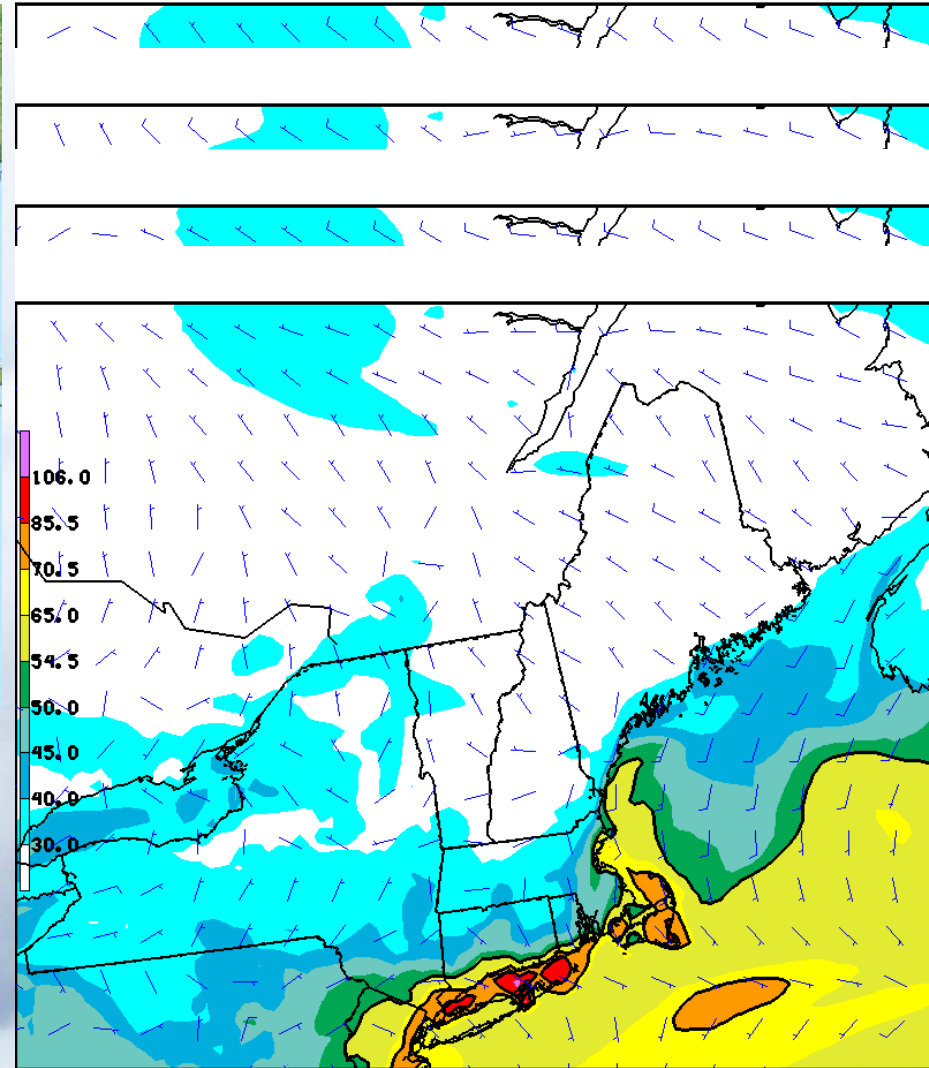

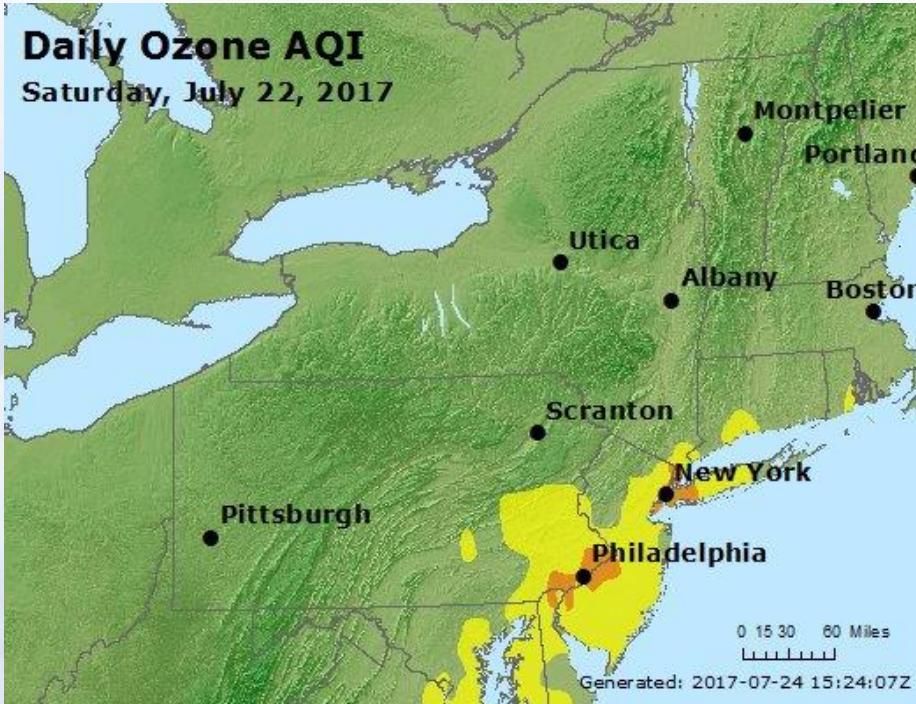

June 22, 2017 24-hour Back Trajectories 4:00pm EST

Low level winds (10-100 meters) were southwesterly over southern CT, traveling over the metro NYC area, which had the greatest impact on our Danbury monitor. It appears that the warm front had penetrated into CT sooner than the models predicted.

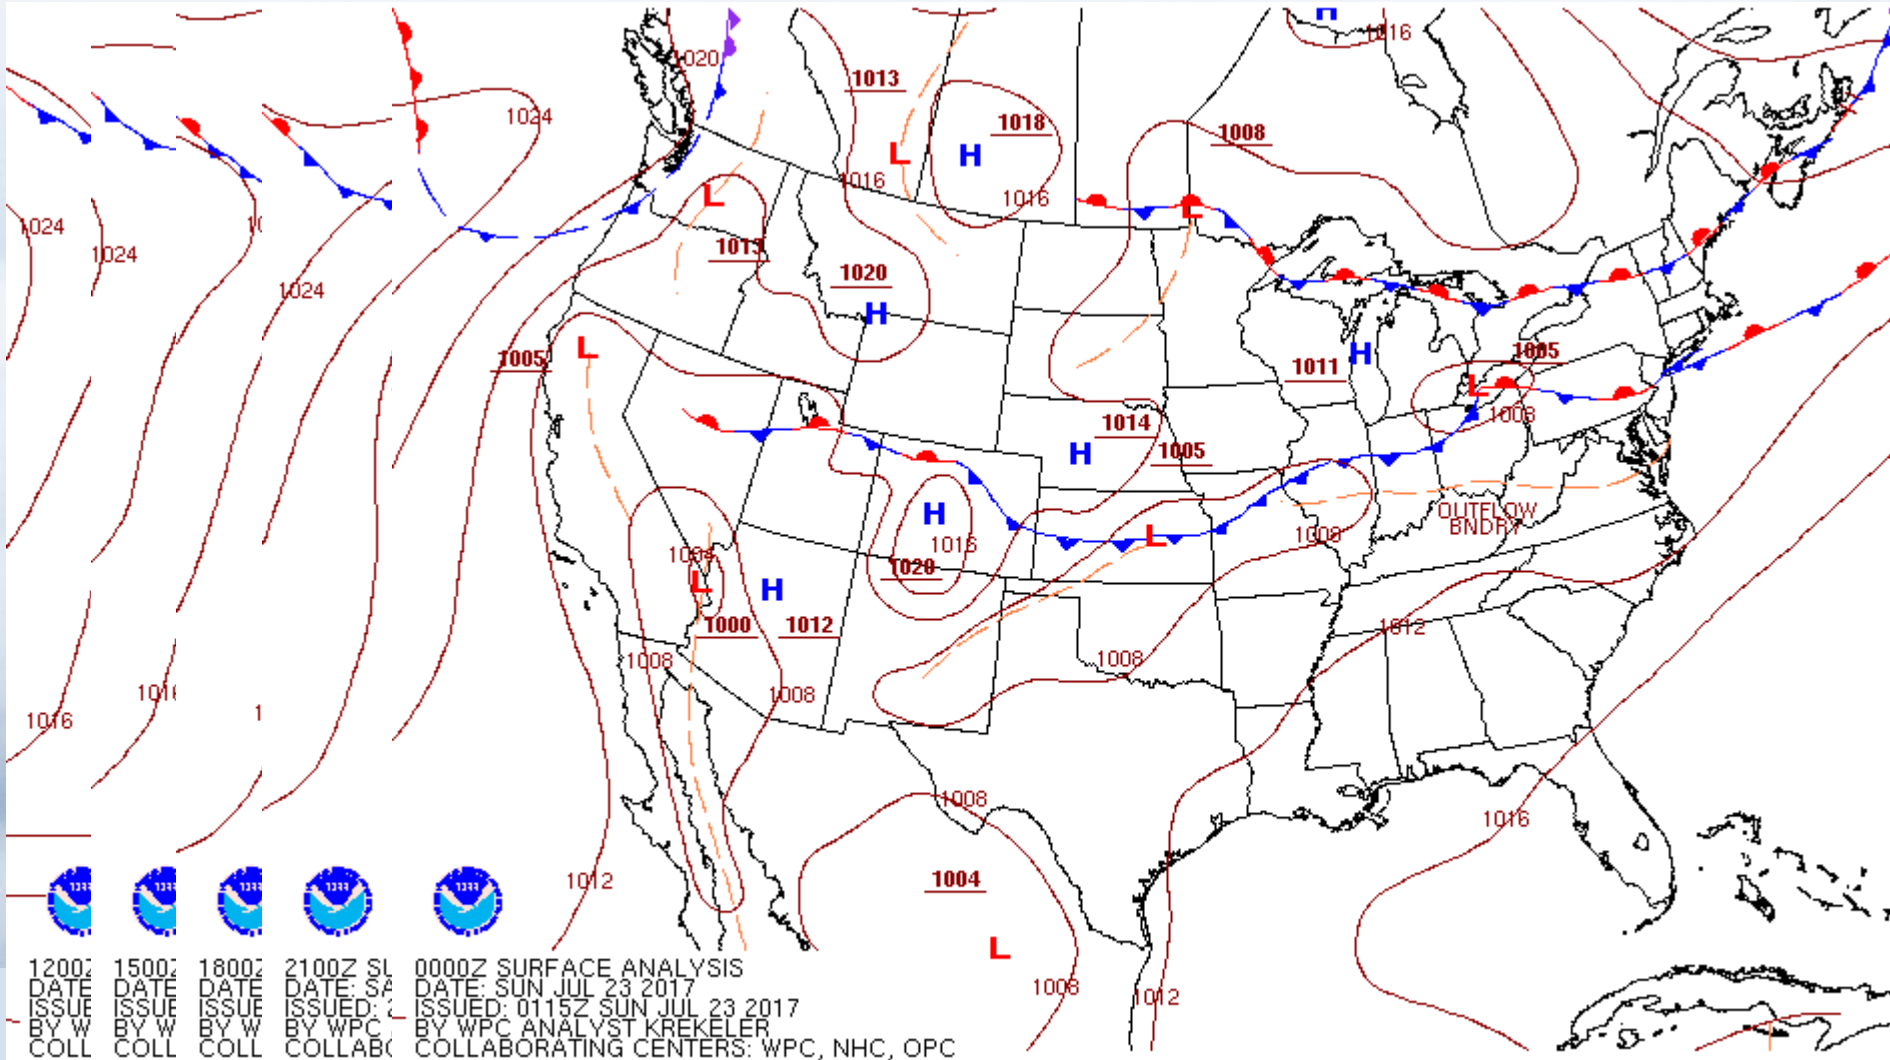

July 22, 2017 Ozone Over Prediction

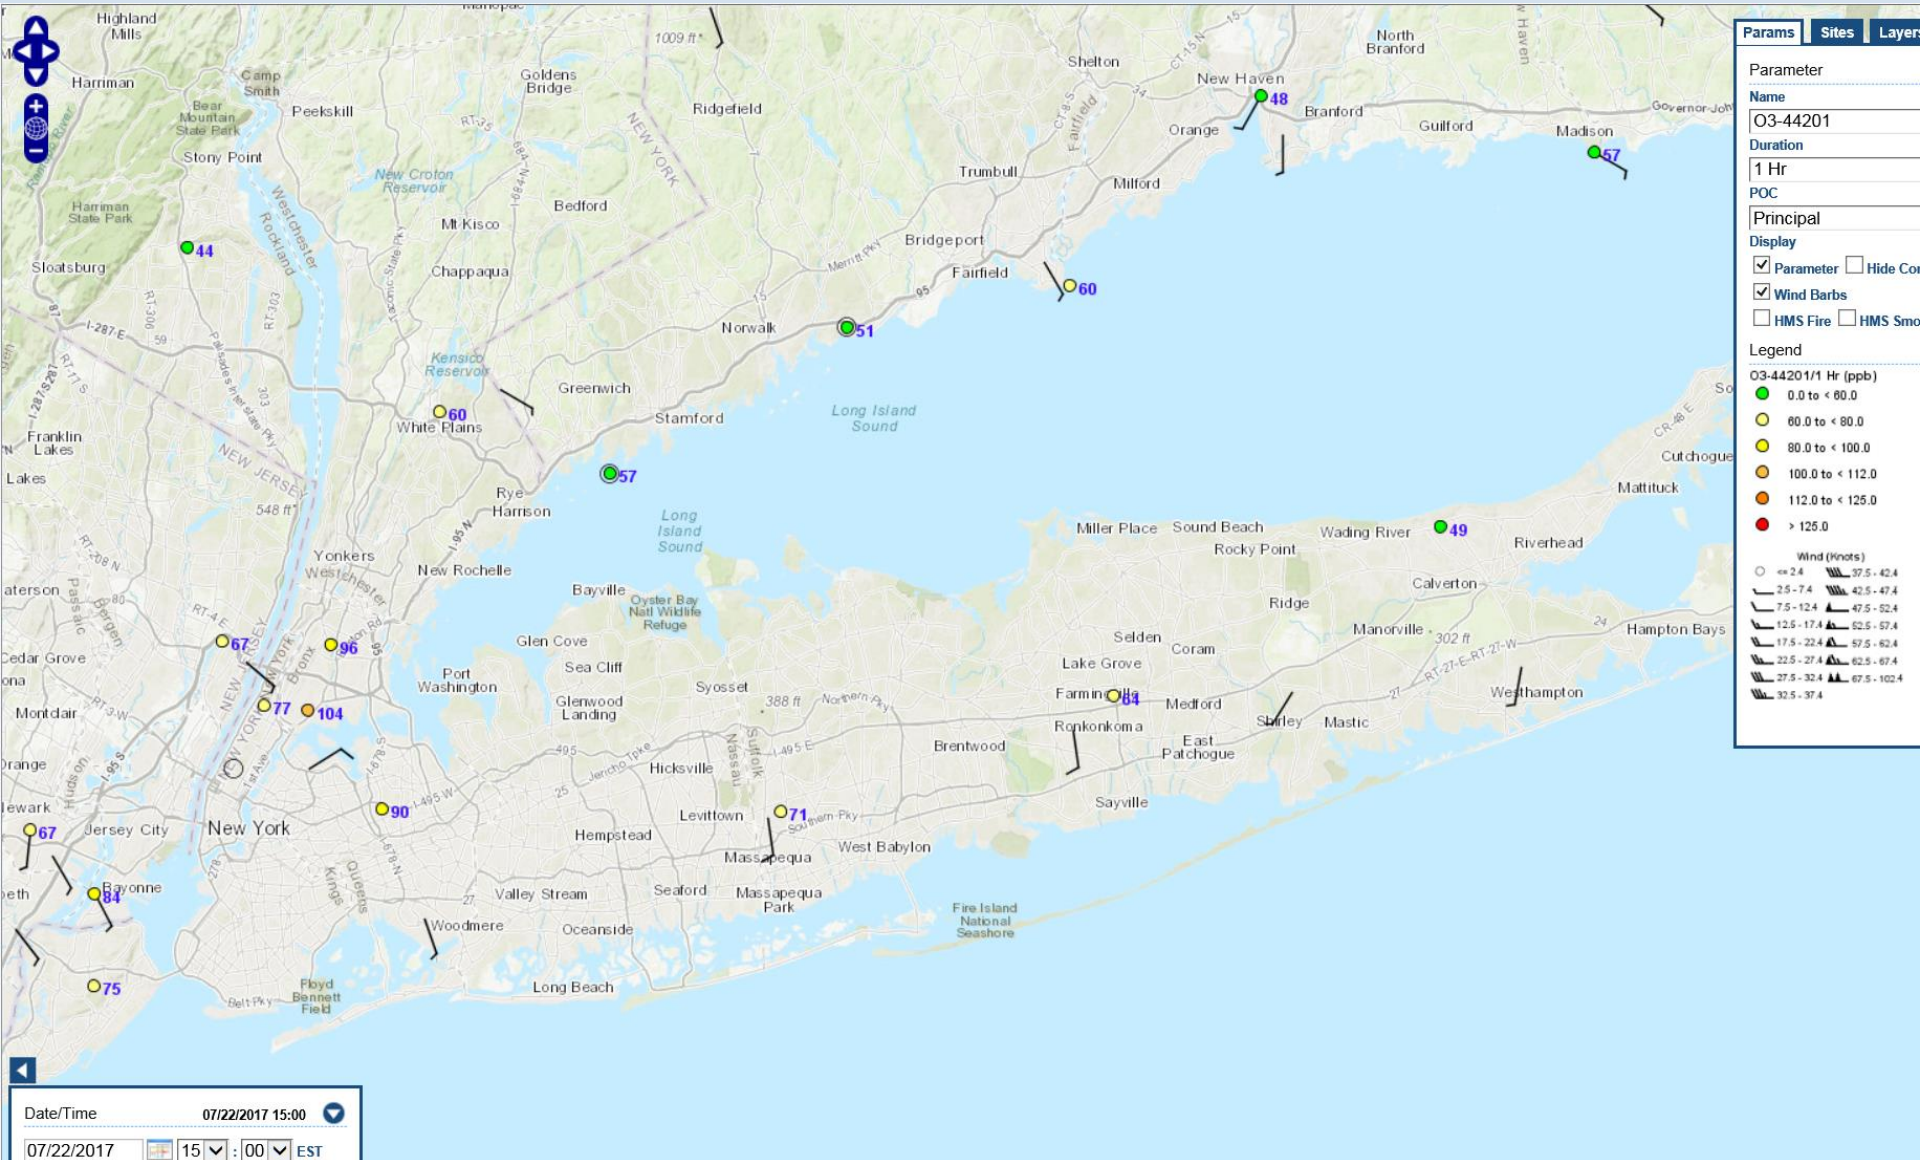

PROD PROD DAY1 OZNX08 20170722 12Z CYC

July 22, 2017 Surface Analysis

- Cold front stalled just south of Connecticut which prohibited a LIS plume to develop.

July 22, 2017 1500EST Ozone

July 22, 2017 NOAA Model

PROD PROD OZCN01 @UN 170723/0300V015 -

July 21, 2017 AOD

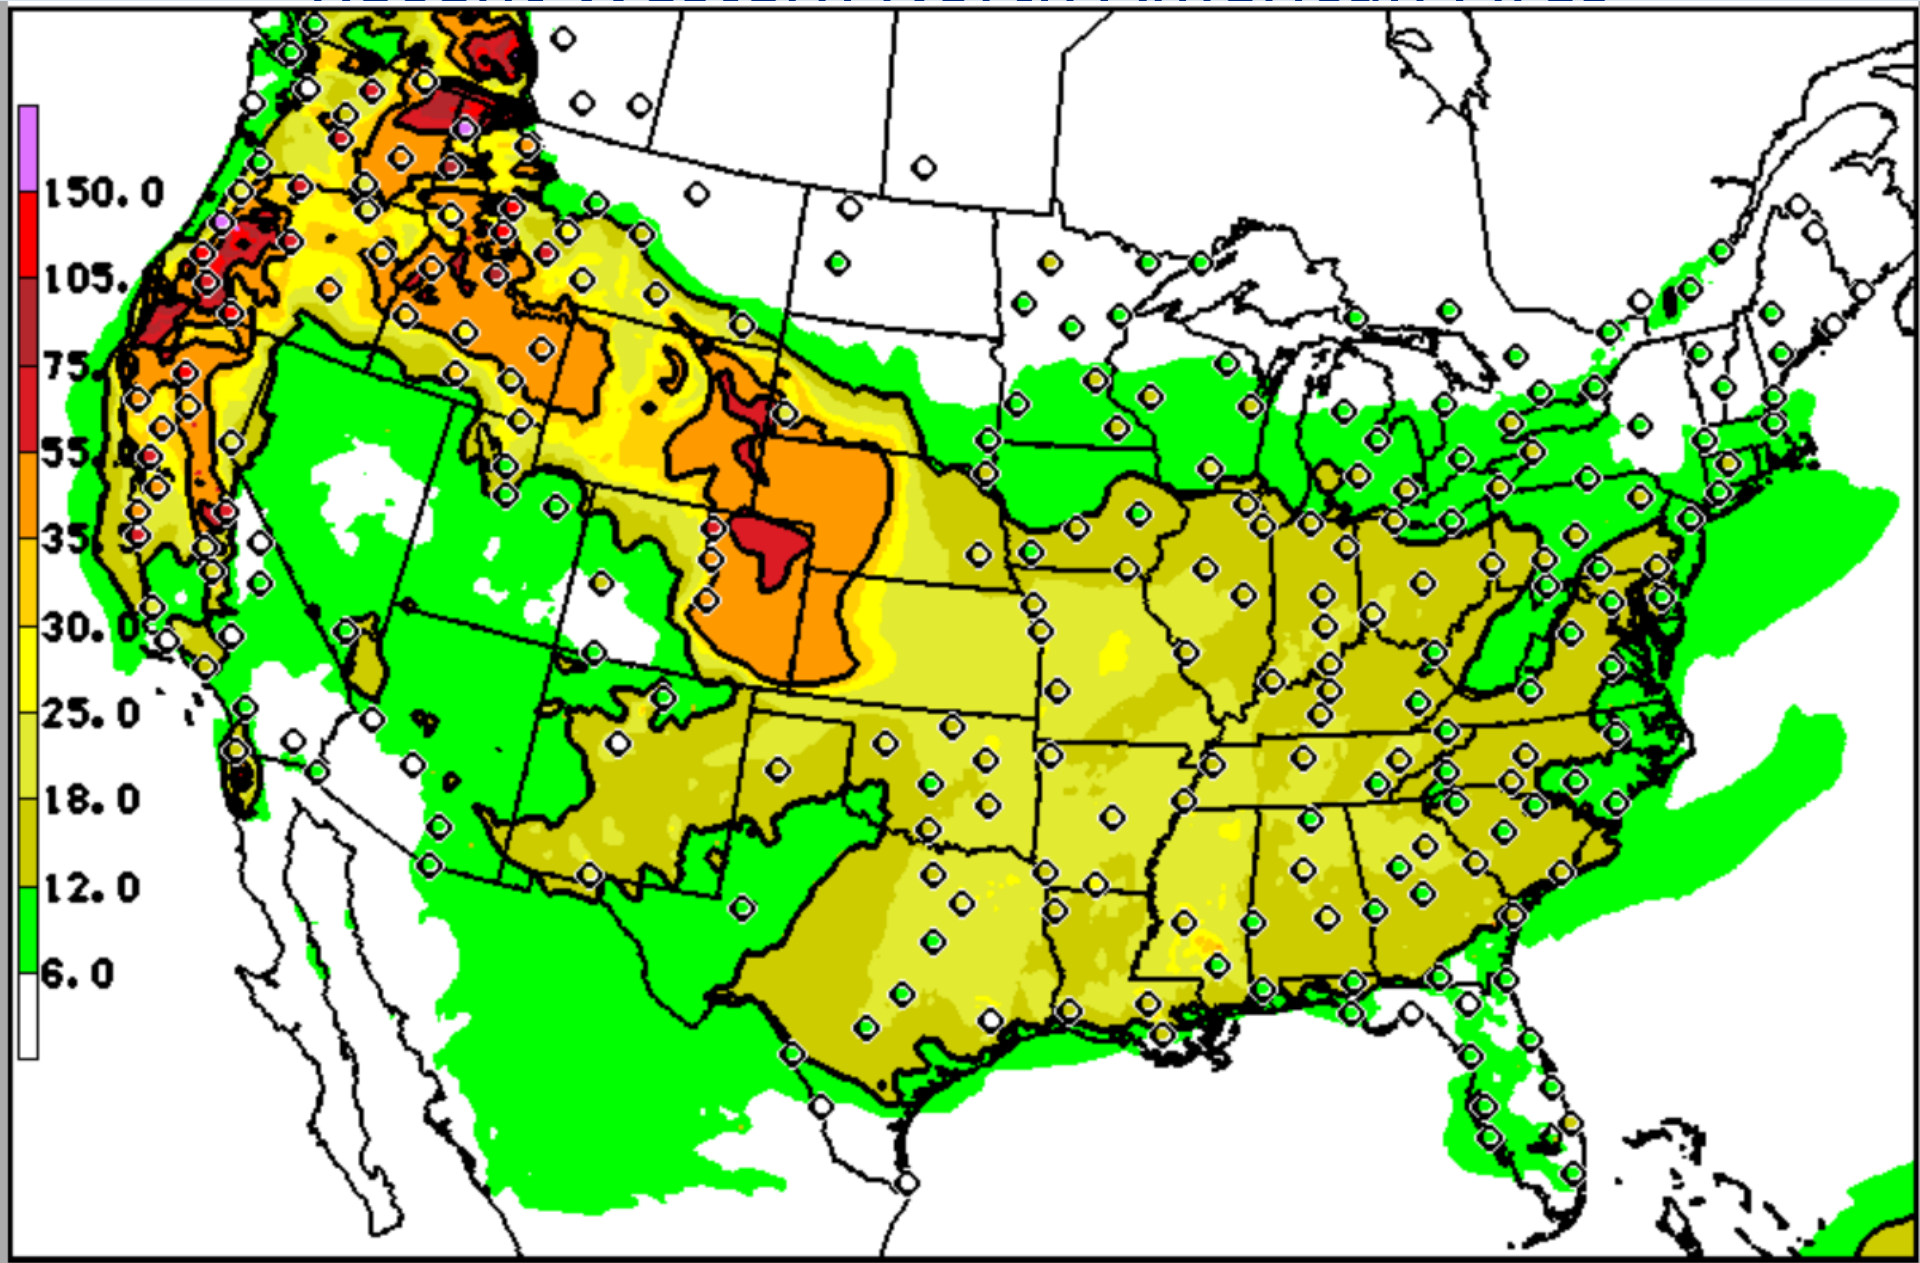

There appears to have been a smoke plume riding up the East Coast the day. Is it possible that the NOAA Model used the particulates to produce a plume of ozone over the Atlantic?

Western Fire Plumes (GOES-16)

- Western Fires created impressive plume on September 4, 2017.

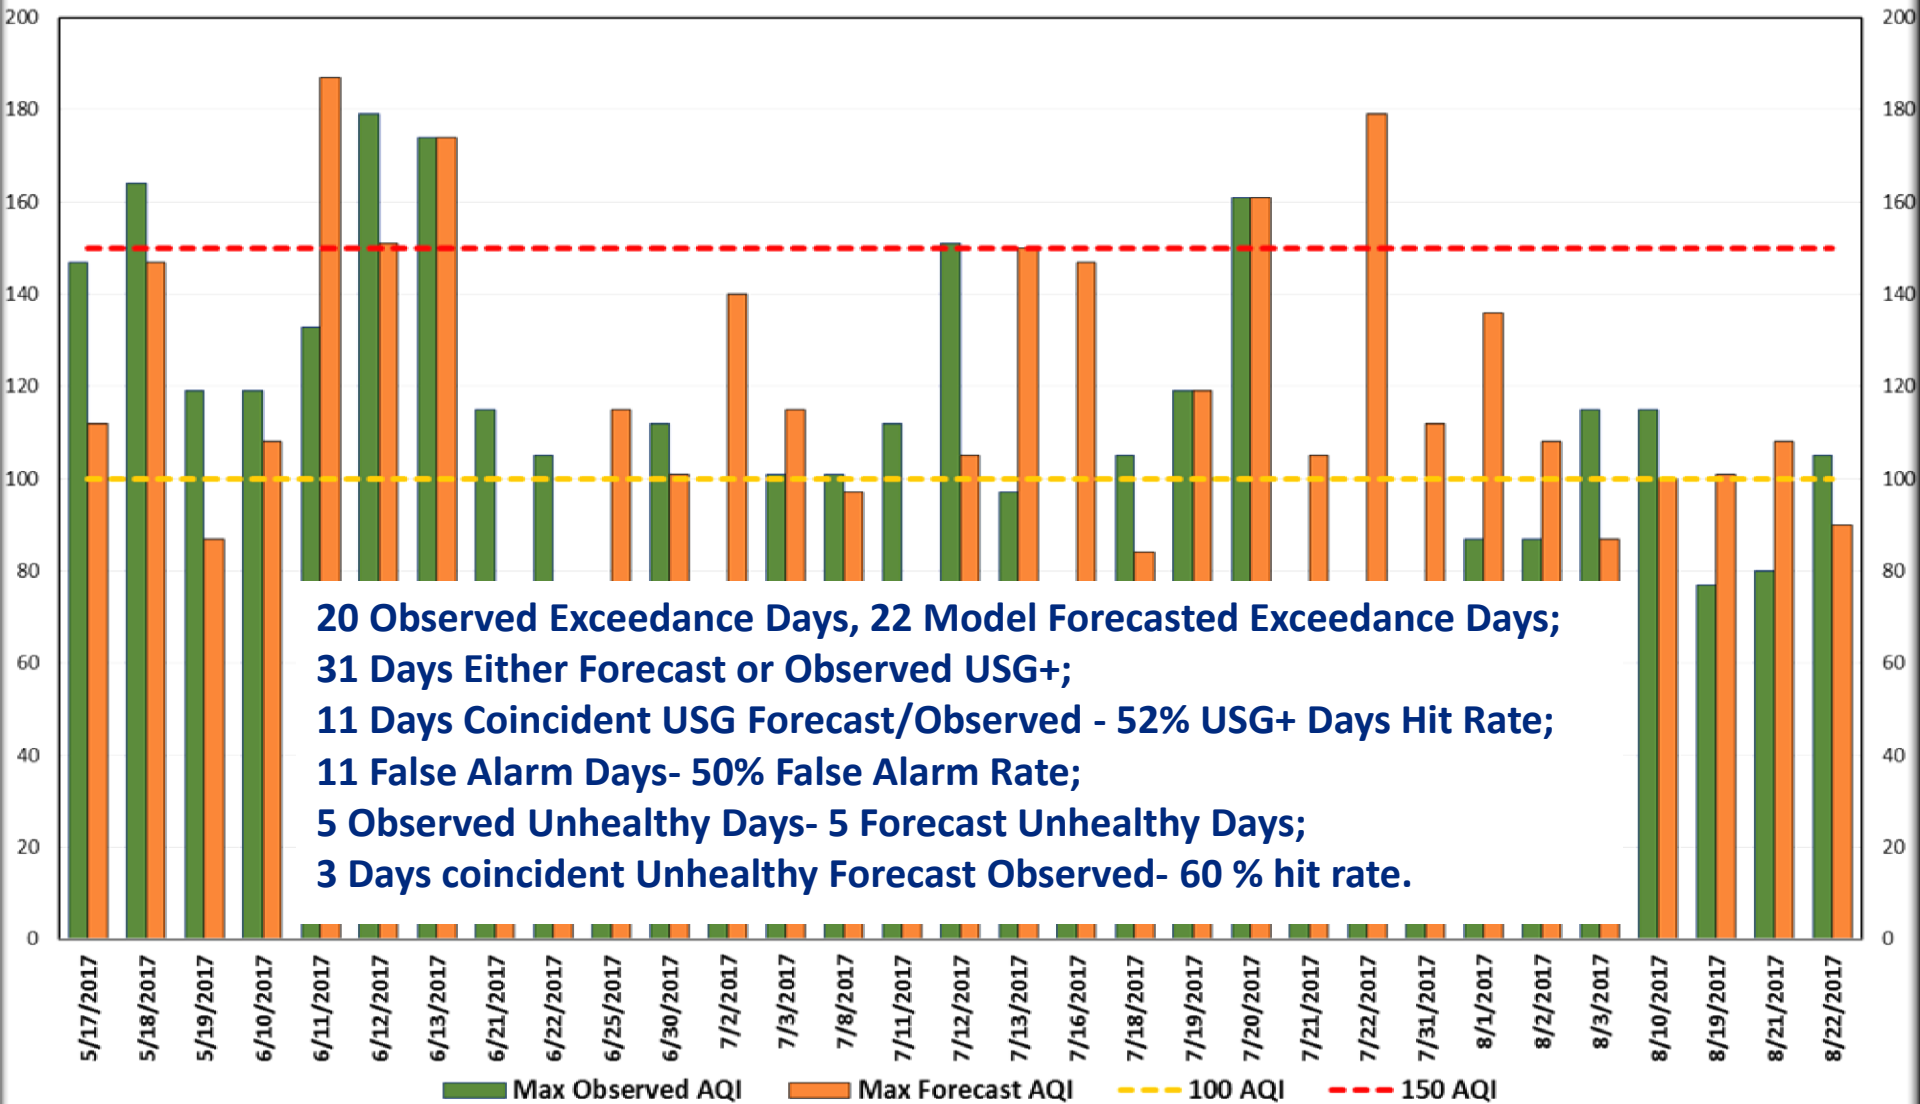

Recent Western North American Fires

PROD PROD DAY2 PMX94 20170903 06Z CYC

Maximum Observed vs. Forecast AQI

Maximum NOAA Forecast AQI vs. Observed Ozone AQI

Conclusions

- 20 exceedance days in 2017, compared with 31 in 2016;
- Highest ozone levels occurred in May-June this year, because of weather pattern changing in July;
- The NOAA model generally under predicted the May- June events, possibly due to smoke from agricultural fires;
- Some over predictions in July may have been due to over development of Mid-Atlantic plume over the ocean.
- The NOAA model is generally a reliable tool for forecasters and would benefit from a high resolution nested area over Long Island Sound.
